We prepared a novel gas separation membrane having both high CO<sub>2</sub> permselectivity and high mechanical strength from a hyper-branched graft polymer synthesized using atom transfer radical polymerization (ATRP) method. A macro-initiator for ATRP was prepared by copolymerization of methyl methacrylate and chloromethylstyrene. The graft polymers were obtained by grafting poly(ethylene glycol)methyl ether methacrylate (POEM) on the macro-initiator by ATRP changing POEM content,  $C_p$ , in the polymers. Self-standing membranes were prepared by casting a tetrahydrofuran solution of the polymers obtained. The permeation experiment at 308K shows that permeability coefficient of CO<sub>2</sub> through the membrane of  $C_p = 72\text{wt}\%$  is  $1.0 \times 10^{-8} \text{ cm}^2 (\text{STP}) \text{ cm}^{-1} \text{ s}^{-1} \text{ cmHg}^{-1}$ , and separation factor of CO<sub>2</sub>/N<sub>2</sub> is 53. The maximum tensile strength of the membrane obtained from a stress-strain curve is 2.7 MPa. These data indicate that the membrane obtained from the hyper-branched graft polymers has an enough performance for CO<sub>2</sub>/N<sub>2</sub> gas separation.

### 1. INTRODUCTION

The greenhouse effect is one of the important issues in the world. A comparison of the relative greenhouse effect of each gas reveals that nearly two-thirds of the total greenhouse effect can be attributed to carbon dioxide. Therefore, a most relevant approach to prevent global warming is regulating CO<sub>2</sub> gas emission. Membrane separation is one of the key technologies to regulate CO<sub>2</sub> gas emission with reduced energy consumption.

There have been many studies on CO<sub>2</sub> selective membranes [1-18]. Ion-exchange or liquid membranes using facilitated transports mechanism of CO<sub>2</sub> [1,2] have shown high permselectivity. However, they have not been applied on a commercial scale because of their

characteristic shortcomings. Solid polymeric membranes such as fluorine-containing polyimides have also been studied [5-11]. However, these polyimides have a low permeability ratio of CO<sub>2</sub> over N<sub>2</sub>. For practical application, it is necessary to develop membrane materials having a much higher performance: e.g.  $P_{\text{CO}_2} > 100$  Barrer (1 Barrer =  $10^{-10} \text{ cm}^2 (\text{STP}) \text{ cm}^{-1} \text{ s}^{-1} \text{ cmHg}^{-1}$ ) and a permeability ratio of CO<sub>2</sub> over N<sub>2</sub>,  $P_{\text{CO}_2} / P_{\text{N}_2} > 70$  [12]. Okamoto *et al.* have reported the excellent performance of CO<sub>2</sub>/N<sub>2</sub> separation by poly(ether imide) segmented copolymers [13-15], for example,  $P_{\text{CO}_2} = 140$  Barrer and  $P_{\text{CO}_2} / P_{\text{N}_2} > 70$  at 298 K [15]. They also have reported excellent gas permeation properties through a membrane using high molecular weight branched

polyethers:  $P_{CO_2} = 770$  Barrer and  $P_{CO_2}/P_{N_2} = 46$  at 308 K [16].

For practical applications of a CO<sub>2</sub> selective membrane in industrial use, both high CO<sub>2</sub> permselectivity and high mechanical strength are needed. In this study, we prepared such a high performance membrane for CO<sub>2</sub> separation from a hyper-branched graft polymer using atom transfer radical polymerization (ATRP) method.

## 2. EXPERIMENTAL

### 2.1 Synthesis of the macroinitiator for ATRP

A macro-initiator for ATRP was prepared by copolymerization of methyl methacrylate (MMA) and chloromethylstyrene (CMS) by a conventional radical polymerization in toluene solvent using 2,2'-azobis isobutyronitrile as an initiator.

### 2.2. Synthesis of a hyper branched graft polymer using ATRP

The graft polymers were obtained by grafting poly(ethylene glycol) methyl ether methacrylate, referred to herein as poly[(oxyethylene)<sub>n</sub> methacrylate] (POEM,  $M_n = 475$ g/mol; Aldrich), macromonomer on the macro-initiator in 1-methyl-2-pyrrolidinone solvent by ATRP using CuCl and 4,4'-dimethyl-2,2'-dipyridyl as catalyst.

### 2.3. Preparation of CO<sub>2</sub> selective membranes

A CO<sub>2</sub> selective membrane was prepared by casting a tetrahydrofuran solution of the polymer obtained on Teflon sheet and by drying it at 30°C for 4 h.

### 2.4 Permeation experiments for CO<sub>2</sub> and N<sub>2</sub> gas.

Permeability coefficients  $P$  and the diffusion time lag  $\theta$  were measured by a vacuum time-lag method at 1 atm and 308 K. The apparent diffusion coefficient  $D$  was calculated from the following equation:

$$D = \frac{d^2}{6\theta} \quad (1)$$

where  $d$  is the membrane thickness. The apparent solubility coefficient  $S$  was evaluated from  $S=P/D$ .

### 2.5 Measurement of the mechanical strength of the membranes

The mechanical strength of the membranes was determined with a table model testing machine (SHIMADZU, EZ-Test500N). In the static stress-strain curves, specimens with a nominal 20-mm-gauge length and 0.2-mm thickness were deformed in tension at a constant strain rate of 10 mm/min at 25 °C, and stress-strain data were determined to failure.

## 3. RESULTS AND DISCUSSION

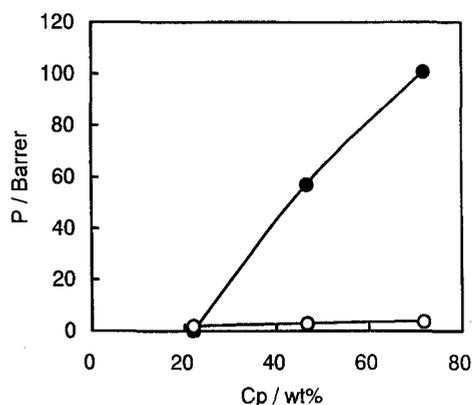

The POEM content,  $C_p$ , calculated from NMR and the tensile strength and Young's modulus obtained from the stress-strain curve of the membranes are listed in Table 1. Both the tensile strength and Young's modulus decrease with increasing  $C_p$ . The tensile strength at  $C_p = 72$ wt% is 2.7 MPa. This means that the sample membranes have enough strength for a membrane for gas separation.

**Table 1** Characteristics of sample membranes

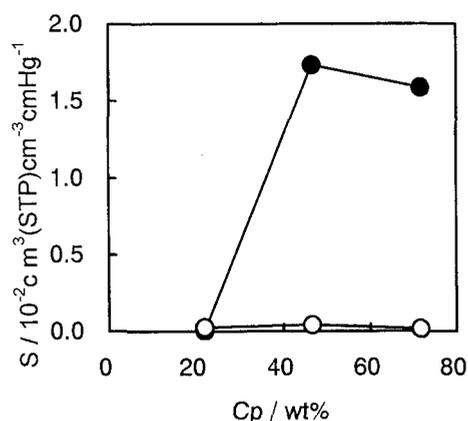

$R_{MI}$  : MMA/CMS mole ratio in the macro initiator,  $Dd$  : membrane thickness,  $C_p$  : POEM content from NMR data,  $\sigma$  : tensile strength,  $E$  : Young's modulus

Sample	$R_{MI}$ [-]	$Dd$ [ $\mu$ m]	$C_p$ [wt%]	$\sigma$ [MPa]	$E$ [MPa]
M1	43	72.0	22	41	1400
M2	140	165	47	4.1	15
M3	150	155	72	2.7	0.29

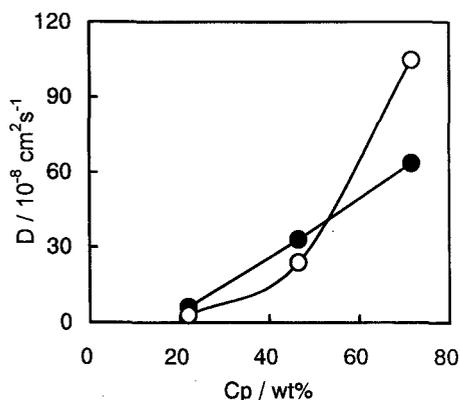

Figure 1 shows the permeability coefficient of CO<sub>2</sub> and N<sub>2</sub> gases as a function of  $C_p$ . The value of the permeability coefficient of CO<sub>2</sub> gas increases with increasing  $C_p$  while that of N<sub>2</sub> gas is almost independent

**Fig.1** Permeability coefficient of CO<sub>2</sub> and N<sub>2</sub> gases as a function of POEM content,  $C_p$ , in the membranes. ●: CO<sub>2</sub>. ○: N<sub>2</sub>.

**Fig.3** Solubility coefficient of CO<sub>2</sub> and N<sub>2</sub> gases as a function of POEM content,  $C_p$ , in the membranes. ●: CO<sub>2</sub>. ○: N<sub>2</sub>.

**Fig.2** Diffusion coefficient of CO<sub>2</sub> and N<sub>2</sub> gases as a function of POEM content,  $C_p$ , in the membranes.

of  $C_p$ . The value of the permeability coefficient of CO<sub>2</sub> gas is 100 Barrer when  $C_p$  is equal to 72 wt%.

Figure 2 shows the diffusion coefficient of CO<sub>2</sub> and N<sub>2</sub> gases as a function of  $C_p$ . The diffusion coefficient of CO<sub>2</sub> gases has almost the same values as that of N<sub>2</sub> gases. The value of the diffusion coefficient of both the gases increases with  $C_p$ .

Figure 3 shows the solubility coefficient of the two gases as a function of  $C_p$ . The solubility coefficient of CO<sub>2</sub> gas is 83 times higher than that of N<sub>2</sub> gas when  $C_p = 73$  wt% although the solubility coefficient of CO<sub>2</sub> gas has less value when  $C_p = 22$  wt%. The high solubility coefficient of the membrane with high POEM content

will due to the high affinity of CO<sub>2</sub> molecules to the POEM segments. This result indicates that the high permeability coefficient of CO<sub>2</sub> through the membrane is due to the high solubility of CO<sub>2</sub> in the membrane.

#### 4. CONCLUSIONS

We prepared a novel CO<sub>2</sub> selective membrane from a hyper-branched graft polymer synthesized by graft polymerization of MMA main chain on POEM graft chains, changing POEM content. The permeability coefficient of CO<sub>2</sub> through the membrane increases with increasing POEM content and has a value of  $1.0 \times 10^{-8}$  cm<sup>3</sup>(STP)cm/(cm<sup>2</sup>scmHg), when  $C_p = 72$  wt%. The separation factor of CO<sub>2</sub>/N<sub>2</sub> also increases with increasing  $C_p$  and is 53 when  $C_p = 72$  wt%. The high permeability of CO<sub>2</sub> gas is due to the high solubility coefficient of CO<sub>2</sub> in the POEM domain. The tensile strength of the membrane decreases with increasing  $C_p$  and is 2.7 MPa when  $C_p = 72$  wt%. Both the high CO<sub>2</sub> permeability and high mechanical strength may come from the microphase-separated structure consisting of rubbery POEM segments and glassy PMMA segments. These results indicate that the membrane obtained from

the hyper-branched graft polymers will have an enough performance for CO<sub>2</sub>/N<sub>2</sub> gas separation.
